Abstract

A new formulation to calculate the shakedown limit load of Kirchhoff plates under stochastic conditions of strength is developed. Direct structural reliability design by chance constrained programming is based on the prescribed failure probabilities, which is an effective approach of stochastic programming if it can be formulated as an equivalent deterministic optimization problem.

We restrict uncertainty to strength, the loading is still deterministic. A new formulation is derived in case of random strength with lognormal distribution. Upper bound and lower bound shakedown load factors are calculated simultaneously by a dual algorithm.

Keywords: Kirchhoff Plate, Limit Analysis, Shakedown Analysis, Primal Dual Programming, Stochastic Programming, Chance Constrained Programming.
1 INTRODUCTION

Plates are very important structural elements, which are widely used in civil and mechanical engineering. The common examples of plates are slabs in civil engineering structures, bearing plate under columns, many parts of mechanical components. In this chapter, we consider bending of such plates subjected to lateral loads. The bending stiffness of a plate depends on the cube of its thickness. The classical theory divides plates into following groups: thin plates with small deflection, thin plates with large deflections, and thick plates.

The following assumptions are made in the small deflections theory of thin plates:

a) There is no deformation in the middle plane of the plate. This plane remains neutral during bending.

b) The normal to the middle plane of the plate remains straight and normal to the deformed middle plane.

c) The normal stresses in the transverse direction to the plate are negligible.

The above assumptions on which A.E.H. Love based his plate theory were proposed by Gustav R. Kirchhoff [1]. Consequently, thin plates with small deflections theory are called Kirchhoff-Love plate or Kirchhoff plate for short. This theory is suitable for plates with length of span at least 10 times the thickness. Many engineering problems lie in the above category and satisfactory results are obtained by the classical thin plates theory.

If the span is less than 10 times the thickness, the thin plates assumptions (a) and (b) no longer apply. The Reissner-Mindlin plate thick plates theory, which accounts for shear deformations, or a three dimensional analysis can be recommended for such plates [12].

Limit analysis of plates in bending has been studied analytically and numerically [11]–[23]. Due to limitations of analytical methods, alternative numerical approaches such as finite element methods (FEM), meshfree methods or isogeometric analysis (IGA) have been developed.

In [24] a dual algorithm has been developed to calculate simultaneously both the upper and lower bounds of the plastic collapse limit and shakedown limit of thin plates. We reformulate a similar algorithm as deterministic equivalent of a chance constrained program in which the lower bound and upper bound limit and shakedown load of plate under uncertain strength is computed.

Limit and shakedown analysis state problems as a mathematical programming. If the strength of a plate is a random variable, we may consider the problems as a stochastic programming problem. Many models of stochastic programming have been proposed such as approximate polyhedral dynamic programming [25]–[27], nominal solutions [28], measurement-based optimization [29], [30], worst-case and distributional robustness analysis [31]–[33], robust optimization [34], recourse programming [35]–[37] and chance constrained optimization (CCOPT) [38], [39]. In this paper the CCOPT approach is used to treat the problem of shakedown analysis of plate under uncertainty condition of strength. If the thickness deterministic and the yield stress is distributed normally or lognormally a deterministic equivalent formulation can be derived, which allows a most effective numerical calculation of limit and shakedown loads for a prescribed failure probability of the structure.

2 BASIC RELATIONS IN THIN PLATE THEORY

In this section the necessary relations are listed using the notations as indicated in the plate element shown in Fig. 1.
Let $u, v$ and $w$ be the displacement at any point $(x, y, z)$ in the plate. Similar to elasticity theory, the inelastic behavior of thin plates is analyzed under Kirchhoff’s assumption that the normal to the middle plane of the plate remains straight and normal to the deformed middle plane. This assumption yields $u = -z \frac{\partial w}{\partial x}$, $v = -z \frac{\partial w}{\partial y}$ and the strains are obtained as

$$
\varepsilon = \begin{bmatrix}
\varepsilon_{xx} & \varepsilon_{xy} \\
\varepsilon_{yx} & \varepsilon_{yy}
\end{bmatrix} = \begin{bmatrix}
\frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} + \frac{\partial v}{\partial y} \\
\frac{\partial v}{\partial x} & \frac{\partial v}{\partial y}
\end{bmatrix} = \begin{bmatrix}
-\frac{\partial^2 w}{\partial x^2} & -z \frac{\partial^2 w}{\partial x \partial y} \\
-\frac{\partial^2 w}{\partial y^2} & -2z \frac{\partial^2 w}{\partial x \partial y}
\end{bmatrix} = z \begin{bmatrix}
\chi_x \\
\chi_y \\
\chi_{xy}
\end{bmatrix}.
$$

(2.1)

Here $\chi = [\chi_x, \chi_y, \chi_{xy}]^T$ is the vector of curvatures. The kinematic relations can be written as follows:

$$
\dot{\chi} = -\nabla^2 \dot{w},
$$

(2.2)

where $\dot{\chi}$ is the curvature rate vector and $\dot{w}$ is the transversal velocity.

### 2.1 Yield criteria

Similar to fully plastic beams, the limit state of greatest load carrying capacity is obtained for a double rectangular distribution of the stresses across the thickness $h$ of the plate. Therefore, the limit values of the bending moments in the $x$ and $y$ directions and of the twisting moment are

$$
M_x = \sigma_x \frac{h^2}{4}, \quad M_y = \sigma_y \frac{h^2}{4}, \quad M_{xy} = \sigma_{xy} \frac{h^2}{4}.
$$

(2.3)
Contrary to the bending of beams, however, the normal stresses $\sigma_x$ and $\sigma_y$ are not equal to the yield limits in uniaxial tension; rather, they must satisfy a yield condition for plane stress, taking into account the in-plane shear stress $\sigma_{xy}$. The out-of-plane shear stresses, $\sigma_{xz}, \sigma_{yz}$ are usually neglected. Consider a general yield condition of the form

$$f(\sigma_x, \sigma_y, \sigma_{xy}) = 0$$

(2.4)

applicable to plane stress states. In a fully plasticized cross section, the stresses $\sigma_x, \sigma_y, \sigma_{xy}$ are constant. Expressing (2.4) in terms of bending and twisting moments, we have the corresponding yield criterion for a plate,

$$f \left( \frac{4M_x}{h^2}, \frac{4M_y}{h^2}, \frac{4M_{xy}}{h^2} \right) = 0.$$

(2.5)

As an illustration, the von Mises yield criterion can be written in the form

$$f(\sigma_x, \sigma_y, \sigma_{xy}) \equiv \sigma_x^2 - \sigma_x \sigma_y + \sigma_y^2 + 3\sigma_{xy}^2 - \sigma_0^2 = 0.$$  

(2.6)

Expressing from (2.6) stresses in terms of moments, the criterion takes the form

$$f(M_x, M_y, M_{xy}) \equiv M_x^2 - M_x M_y + M_y^2 + 3M_{xy}^2 - M_0^2 = 0$$

(2.7)

in which

$$M_0 = \sigma_0 \frac{h^2}{4}.$$  

(2.8)

In matrix form, the von Mises yield criterion can be written as follows:

$$f(\mathbf{m}) = \sqrt{\mathbf{m}^T \mathbf{P} \mathbf{m}} - m_0 = 0,$$

(2.9)

where $\mathbf{m} = \{M_x, M_y, M_{xy}\}^T$ is the vector of bending and twisting moments, $m_0 = M_0$ is the fully plastic limit moment per unit length of a plate section and $\sigma_0$ is the uniaxial yield stress of material,

$$\mathbf{P} = \frac{1}{2} \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & 0 \\ 0 & 0 & 6 \end{bmatrix}.$$  

(2.10)

A more complex yield surface of plates and shells has been considered in [40].

3 STATIC APPROACH WITH CHANCE CONSTRAINED PROGRAMMING

Consider a convex polyhedral load domain $\mathcal{L}$ and a special loading path consisting of all load vertices $P_k (k = 1, \ldots, m)$ of $\mathcal{L}$. The total moment $\mathbf{m}(\mathbf{x}, t)$ at a point $\mathbf{x} \in \Omega$ of the considered plate $\mathcal{P}$ at time $t$ is decomposed into an elastic reference moment $\mathbf{m}^E(\mathbf{x}, t)$ and a residual moment $\mathbf{p}(\mathbf{x}, t)$. Here, $\mathbf{m}^E(\mathbf{x}, t)$ denotes the fictitious moment that would appear in a purely elastic reference structure $\mathcal{P}^E$ under the same loading conditions as the original struc-
ture, and $\rho(x,t)$ represents a residual moment field that is induced by the evolution of plastic strains

$$m(x,t) = m^E(x,t) + \rho(x,t). \quad (3.1)$$

According to Melan’s static shakedown theorem the structure will shakedown, if there exists a time-independent residual moment field $\bar{\rho}(x)$ such that the yield condition is satisfied for any loading path at any time $t$ and in any point $x$ of the plate. Based on this lower bound theorem, for a plate made up of elastic perfectly plastic material, the maximum enlarging of the load domain allowing still for shakedown, characterized by load factor $\alpha^-$ that can be obtained by solving the following optimization problem:

$$\alpha^- = \max \alpha \quad \text{s.t.:} \begin{cases} \nabla^2 \bar{\rho}(x) = 0 & \text{in } \Omega \\ f\left[\alpha m^E(x,t) + \bar{\rho}(x)\right] \leq m_0 \end{cases} \quad (3.2)$$

By discretizing the entire problem domain $\Omega$ into finite elements and applying the Gauss-Legendre integration technique, eqs. (3.2) can be rewritten in the following form:

$$\alpha^- = \max \alpha \quad \text{s.t.:} \begin{cases} \sum_{i=1}^{NG} w_i B_i^T \bar{\rho}_i = 0 & \text{in } \Omega \\ f(\alpha m^E_k + \bar{\rho}_i) \leq m_0 & \forall i = 1, NG \\ \forall k = 1, m \end{cases} \quad (3.3)$$

in which $B_i$ is the deformation matrix, $w_i$ is integration weight at Gauss point $i$ and $NG$ denotes the total number of Gauss points of the structure.

Let us now consider the situation that the plastic moment of the plate is not given but must be modelled $m_0 = m_0(\omega)$ a random variable on a certain probability space. Under uncertainty, the inequalities in (3.3) are not always satisfied, the probability of the $i^{th}$ yield condition is required to be satisfied is greater than some reliability level $\psi_i$. Problem (3.3) becomes a chance constraint stochastic program:

$$\alpha^- = \max \alpha \quad \text{s.t.:} \begin{cases} \sum_{i=1}^{NG} w_i B_i^T \bar{\rho}_i = 0 & \text{in } \Omega \\ \text{Prob} \left[ f(\alpha m^E_k + \bar{\rho}_i) - m_0(\omega) \leq 0 \right] \geq \psi_i & \forall i = 1, NG \\ \forall k = 1, m \end{cases} \quad (3.4)$$

Let the plastic moment $m_i(\omega)$ be distributed normally with mean $\mu_i$ and standard deviation $\sigma_i$, in short $m_i(\omega) \sim \mathcal{N}(\mu_i, \sigma_i^2)$. Based on the methodology of chance constrained programming, problem (3.4) can be converted into a equivalent deterministic program as shown in [10], [11]:

327
\[ \alpha^- = \max \alpha \]

\[ \text{s.t.:} \quad \sum_{i=1}^{NG} w_i B_i^T \mathbf{p}_i = 0 \quad \text{in } \Omega \]

\[ f(\alpha m_i^k + \mathbf{p}_i) \leq \mu_i - \kappa \sigma_i \quad \forall i = 1, NG \quad \forall k = 1, m \]

where \( \kappa = \Phi^{-1}(\nu_i) \) is the inverse normal cumulative distribution function (normal quantile function) of the plastic moment at Gauss point \( i \).

Let the plastic moment \( m_i(\omega) \) be distributed lognormally. This means that \( \ln [m_i(\omega)] \) is distributed normally with mean \( \mu_i \) and standard deviation \( \sigma_i \), in short \( \ln [m_i(\omega)] \sim \mathcal{N}(\mu_i, \sigma_i^2) \). The stochastic program (3.4) can be relaxed into an equivalent deterministic optimization problem after some transformations [2,3]:

\[ \alpha^- = \max \alpha \]

\[ \text{s.t.:} \quad \sum_{i=1}^{NG} w_i B_i^T \mathbf{p}_i = 0 \quad \text{in } \Omega \]

\[ f(\alpha m_i^k + \mathbf{p}_i) \leq e^{\mu_i - \kappa \sigma_i} \quad \forall i = 1, NG \quad \forall k = 1, m \]

4 KINEMATIC APPROACH WITH CHANCE CONSTRAINED PROGRAMMING

An upper bound to the shakedown limit of plates can be obtained using the kinematic shakedown theorem which has following two statements:

**Upper bound:** Shakedown will occur for a structure subject to repeated or cyclic loads, if the rate of plastic dissipation power exceeds the work rate of external forces for any admissible plastic strain-rate cycles and all loading paths.

**Lower bound:** Shakedown cannot occur, if the rate of plastic dissipation power is less than the work rate of external forces for any one admissible plastic strain-rate cycle or any one loading path.

In this investigation, we use von Mises yield criterion. The power of plastic dissipation per unit area of the plate can be formulated as a function of strain rate:

\[ \dot{D}_p = \alpha_0 \sqrt{\dot{e}'Q\dot{e}} \]

where (with (2.10))

\[ Q = P^{-1} = \begin{bmatrix} 4 & 2 & 0 \\ 2 & 4 & 0 \\ 3 & 0 & 1 \end{bmatrix} \]

The plastic dissipation power of the plate domain \( \Omega \) can be written

\[ \dot{D}_{pl}(\dot{\chi}) = \int \int_{\Omega - k/2} \dot{D}_p d\mathbf{z} d\Omega = m_0 \int \int_{\Omega - k/2} \sqrt{\dot{\chi}'Q\dot{\chi}} d\mathbf{z} d\Omega \]

in which \( m_0 \) is the plastic limit moment per unit length of a plate section is computed as (2.8)
We introduce here an admissible cycle of a plastic curvature field $\Delta \chi^p$. At each load vertex, the plastic curvature rate may not necessarily be compatible at each instant during the time cycle, but the plastic curvature accumulation over the cycle is required to be kinematically compatible such that

$$\Delta \chi^p = \sum_{k=1}^m \dot{\chi}^p = \nabla^2 \dot{w} \quad (4.4)$$

Based on the above statements and the mathematical programming theory, an upper bound of the shakedown load factor can be found by solving the following convex nonlinear programming (the superscript $p$ is neglected for simplicity):

$$\alpha^+ = \min \sum_{k=1}^m \int_{\Omega} \dot{D}_{m}(\dot{\chi}) d\Omega$$

s.t.:

$$\Delta \chi^p = \sum_{k=1}^m \dot{\chi} = \nabla^2 \dot{w} \quad \text{in } \Omega$$

$$\dot{w} = 0 \quad \text{on } \partial \Omega$$

$$\sum_{k=1}^m \int_{\Omega} m^E(x, \dot{P}_k) \dot{\chi}^T d\Omega = 1$$

We denote the nodal variables of the finite element by $u = \begin{bmatrix} w & \partial w/\partial x & \partial w/\partial y \end{bmatrix}^T$. The discretized formulation by FEM is as follows:

$$\alpha^+ = \min \sum_{k=1}^m \sum_{i=1}^{NG} w_i m_i \sqrt{\dot{\chi}_i} Q \dot{\chi}_i$$

s.t.:

$$\sum_{k=1}^m \dot{\chi}_i = B_i \dot{u} \quad \forall i = 1, NG \quad (4.6)$$

If the yield stress of the material is random, then the plastic moment is an uncertain quantity and the objective function of (4.6) is a stochastic variable. Firstly, we must properly define the minimum of a random function. This can be done in such a way that one looks for a minimum lower bound $\eta$ of the objective function under the constraint that the probability of violation of that bound is prescribed in [39]

$$\min \eta$$

$$\text{Prob} \left( \sum_{k=1}^m \sum_{i=1}^{NG} w_i m_i(\omega) \sqrt{\dot{\chi}_i} Q \dot{\chi}_i \geq \eta \right) = \psi \quad (4.7)$$

s.t.:

$$\sum_{k=1}^m \dot{\chi}_i = B_i \dot{u} \quad \forall i = 1, NG$$

$$\sum_{k=1}^m \sum_{i=1}^{NG} w_i \dot{\chi}_i m_i^E = 1$$

Problem (4.7) is a stochastic program, which can be converted into an equivalent deterministic program by using a chance constrained programming technique [10], [11].
\[
\alpha^* = \min \sum_{k=1}^{m} \sum_{i=1}^{NG} w_i (\mu_i - \kappa \sigma_i) \sqrt{\mathbf{k}_{ik}^T \mathbf{Q} \mathbf{k}_{ik}}
\]
\[
\sum_{k=1}^{m} \mathbf{k}_{ik} = \mathbf{B} \mathbf{u} \quad \forall i = 1, NG
\]  
\[
\sum_{k=1}^{m} \sum_{i=1}^{NG} w_i \mathbf{k}_{ik}^T \mathbf{m}_{ik} = 1
\]

(4.8)

In case of a lognormal distribution of strength, the stochastic problem (4.7) can be converted into the equivalent deterministic program (4.9) by using the duality property [3]:

\[
\alpha^* = \min \sum_{k=1}^{m} \sum_{i=1}^{NG} w_i e^{(\mu_i - \kappa \sigma_i)} \sqrt{\mathbf{k}_{ik}^T \mathbf{Q} \mathbf{k}_{ik}}
\]
\[
\sum_{k=1}^{m} \mathbf{k}_{ik} = \mathbf{B} \mathbf{u} \quad \forall i = 1, NG
\]  
\[
\sum_{k=1}^{m} \sum_{i=1}^{NG} w_i \mathbf{k}_{ik}^T \mathbf{m}_{ik} = 1
\]

(4.9)

5 A DUAL ALGORITHM FOR SHAKEDOWN ANALYSIS OF A KIRCHHOFF PLATE

For the sake of simplicity, we set some new notations:

\[
\mathbf{k}_{ik} = w_i Q^{1/2} \mathbf{A}_{ik}, \quad \mathbf{t}_{ik} = \left( Q^{1/2} \right)^T \mathbf{m}_{ik}^E, \quad \mathbf{B}_j = w_i Q^{1/2} \mathbf{B}_j,
\]

(5.1)

where

\[
Q^{1/2}Q^{-1/2} = \mathbf{I}, \quad Q = \left( Q^{1/2} \right)^T Q^{1/2}.
\]

(5.2)

By substituting (5.1) into (4.10) one obtains a simplified version for the upper bound of the shakedown limit load (primal problem)

\[
\alpha^* = \min \sum_{k=1}^{m} \sum_{i=1}^{NG} e^{(\mu_i - \kappa \sigma_i)} \sqrt{\mathbf{k}_{ik}^T \mathbf{k}_{ik}}
\]
\[
\sum_{k=1}^{m} \mathbf{k}_{ik} - \mathbf{B} \mathbf{u} = 0 \quad \forall i = 1, NG
\]  
\[
\sum_{k=1}^{m} \sum_{i=1}^{NG} \mathbf{k}_{ik}^T \mathbf{t}_{ik} - 1 = 0
\]

(5.3)

In order to allow a direct nonlinear of the nonsmooth optimization problem, a ‘smooth regularization method’ can be used for overcoming this technical problem. For this purpose, a very small positive number \(\varepsilon_0^2\) is added to \(D_{int}(\mathbf{k}_{ik})\). An efficient technique for large-scale optimization problems, which are successfully applied in [9] is used. Using a penalty method to eliminate the first constraint in (5.3) leads to the penalty function

\[
F_p = \sum_{i=1}^{NG} \left\{ \sum_{k=1}^{m} e^{(\mu_i - \kappa \sigma_i)} \sqrt{\mathbf{k}_{ik}^T \mathbf{k}_{ik} + \varepsilon_0^2} + \frac{c}{2} \left( \sum_{k=1}^{m} \mathbf{k}_{ik}^T \mathbf{u} \right)^T \left( \sum_{k=1}^{m} \mathbf{k}_{ik} - \mathbf{B} \mathbf{u} \right) \right\}.
\]

(5.4)
where \( c \) is a penalty parameter such that \( c \gg 1 \). The corresponding Lagrange function of (5.4) is

\[
L = F_p - \alpha \left( \sum_{i=1}^{NG} \sum_{k=1}^{m} k_{ik}^{T} t_{ik} - 1 \right).
\]

(5.5)

We denote

\[
\hat{\beta}_i = -c \left( \sum_{k=1}^{m} k_{ik} - \hat{B}_i \hat{u} \right).
\]

(5.5)

By employing Newton method to solve the Karush-Kuhn-Tucker (KKT) conditions of the Lagrange function (4.17) and after some manipulations, one gets the following system:

\[
K d \hat{u} = -K \hat{u} + f_1 + f_2 (\alpha + d\alpha),
\]

(5.6)

in which

\[
K = \sum_{i=1}^{NG} \hat{B}_i^{T} E_j^{-1} \hat{B}_j,
\]

\[
f_1 = -\sum_{i=1}^{NG} \hat{B}_i^{T} E_j^{-1} \sum_{k=1}^{m} M_{ik}^{-1} (\hat{\beta}_i + \alpha \hat{t}_{ik}) \frac{t_{ik}^{T} k_{ik}^{T}}{\sqrt{k_{ik}^{T} k_{ik} + \varepsilon_0^2}},
\]

\[
f_2 = \sum_{i=1}^{NG} \hat{B}_i^{T} E_j^{-1} \sum_{k=1}^{m} M_{ik}^{-1} \frac{t_{ik}^{T} k_{ik}^{T}}{\sqrt{k_{ik}^{T} k_{ik} + \varepsilon_0^2}}
\]

and

\[
M_{ik} = e^{(\mu - \kappa) I} + (\hat{\beta}_i + \alpha \hat{t}_{ik}) \frac{k_{ik}^{T}}{\sqrt{k_{ik}^{T} k_{ik} + \varepsilon_0^2}}.
\]

\[
E_j = \frac{I}{c} + \sum_{k=1}^{m} M_{ik}^{-1} \frac{k_{ik}^{T}}{\sqrt{k_{ik}^{T} k_{ik} + \varepsilon_0^2}}.
\]

(5.7)

(5.8)

The system (4.19) with the two last terms on the right-hand side may be interpreted as the linear system arising in purely elastic computations with the global stiffness matrix \( K \). The matrix \( E_j^{-1} \) plays the role of the elastic matrix. Solving this system by the same procedure as for the purely elastic calculation will ensure the kinematic boundary condition for the displacement rate to be satisfied automatically. We have the incremental vectors of nodal variables \( \hat{u} \), curvature rate \( \hat{K}_{ik} \) and \( \hat{\beta}_i \) as follows:

\[
d\hat{u} = d\hat{u}_t + d\hat{u}_c (\alpha + d\alpha)
\]

\[
d\hat{K}_{ik} = (d\hat{K}_{ik})_t + (d\hat{K}_{ik})_c (\alpha + d\alpha)
\]

\[
d\hat{\beta}_i = (d\hat{\beta}_i)_t + (d\hat{\beta}_i)_c (\alpha + d\alpha)
\]

(5.9)

where
\[ d\hat{u}_1 = -\hat{u} + K^{-1}f_1 \]
\[ d\hat{u}_2 = K^{-1}f_2 \]
\[
\begin{align*}
(d\hat{k}_{ik})_1 &= -M_{ik}^{-1}\sqrt{k_{ik}^2 + \varepsilon_{0}^2} (d\beta_i)_1 - M_{ik}^{-1} (m_{ik}k_{ik} + \sqrt{k_{ik}^2 + \varepsilon_{0}^2} \beta_i) \\
(d\hat{k}_{ik})_2 &= -M_{ik}^{-1}\sqrt{k_{ik}^2 + \varepsilon_{0}^2} (d\beta_i)_2 - M_{ik}^{-1} \sqrt{k_{ik}^2 + \varepsilon_{0}^2} t_{ik} \\
(d\beta_i)_1 &= -E_i^{-1} \sum_{k=1}^{m} M_{ik}^{-1} m_{ik} k_{ik} - E_i^{-1} \left[ \hat{B}_i d\hat{u}_1 - \left( \sum_{k=1}^{m} k_{ik} - \hat{B}_i \hat{u} \right) \right] - \beta_i \\
(d\beta_i)_2 &= -E_i^{-1} \hat{B}_i d\hat{u}_2 - E_i^{-1} \sum_{k=1}^{m} M_{ik}^{-1} \sqrt{k_{ik}^2 + \varepsilon_{0}^2} t_{ik}
\end{align*}
\]

and
\[
\alpha + d\alpha = \frac{\sum_{i=1}^{NG} \sum_{k=1}^{m} t_{ik}^{T} \left[ k_{ik} + (d\hat{k}_{ik})_1 \right]}{\sum_{i=1}^{NG} \sum_{k=1}^{m} t_{ik}^{T} (d\hat{k}_{ik})_2} \tag{5.11}
\]

The vectors \( d\dot{q}, d\dot{k}_{ik}, d\beta_i \) and \( d\alpha \) are actually Newton directions, which assure that a suitable step along them will lead to a decrease of the objective function of the primal problem (5.3) and to an increase of the objective function of the dual problem (3.8). Based on (5.9-5.11) we can update the vectors of \( \dot{q}, \dot{k}_{ik}, \beta_i \) and \( \alpha \). The dual algorithm for limit and shakedown analysis is presented in detail in [3].

6 NUMERICAL EXAMPLES

We investigate a L-shape plate subjected to uniform pressure. Length \( L = 10 \text{m} \), plate thickness \( t = 0.1 \text{m} \), the mean value of yield stress \( E(\sigma_0) = 250 \text{MPa} \) and the standard deviation \( \sigma = 0.1E(\sigma_0) \). The reliability level is assumed \( \psi = 0.9999 \). Let us calculate limit and shakedown load factors.
Figure 3: Convergence of limit load factors

Figure 4. L-shape Plate: rounding at the corner
For shakedown analysis, the stress singularity at the sharp reentrant corner has to be removed by rounding the plate at the corner as shown in Figure 4. The FE mesh is made with 380 DKQ elements. Table 2 shows the limit and shakedown load factors if a uniform load varies in the domain $q = [0 1]$. If we compare with the upper and lower bounds in Table 2, the limit load factors are similar. The convergence of shakedown load factors is shown in Figure 5.

7 CONCLUSIONS

Reliability analysis of plates and shells calculates the failure probability after structural design for a given loading [13]. We have presented a probabilistic design method for plates, which allows the most effective numerical calculation of limit and shakedown loads for a prescribed failure probability of the structure with stochastic plastic moment. The implementation of the extension to stochastic loading, obtained in [2], is under preparation. The stochastic programming approach can be proposed as a method for structural optimization. Shakedown analysis has the advantage that it yields a design, which is optimum for all possible time-variant loadings in a considered load domain [41], [42].
